

Year 8 - Unit 13: Expressions, equations & inequalities

Learning Journey:

Prior Learning

- Solve one- and two-step equations, simplify algebraic expressions and perform the four operations with fractions.
- Understand decimal notation, equivalent fractions and basic index laws.

By the end of this unit, you should be able to:

- Solve and represent linear inequalities, expand double brackets and simplify algebraic fractions.
- Convert fractions to recurring decimals and perform calculations involving fractions and algebraic fractions.

Next Steps

- Solve quadratic expressions and equations using factorisation and algebraic manipulation.
- Apply algebraic reasoning to GCSE topics including functions, graphs and more complex fraction problems.

Keywords:

Inequality – A statement comparing values using $<$, $>$, $\leq$ or $\geq$.

Recurring decimal – A decimal with one or more digits that repeat forever.

Double brackets – Two brackets multiplied together.

Algebraic fraction – A fraction containing algebraic expressions.

Factorise – Write an expression as a product of factors.

Reciprocal – The value of 1 divided by a number.

Reading and drawing inequalities on number lines

An **open circle** means that the value is **not included**:

A **filled in circle** means that the value is **included**:

Solving linear inequalities

To solve an **inequality** we calculate the values that an unknown variable can be in that inequality.

Example $2x + 1 < 9$
 $2x < 8$
 $x < 4$

Multiplying or dividing by a negative number **changes the direction of the inequality**.

Example $1 - 2x < 9$
 $-2x < 8$
 $x > -4$

Expanding double brackets

FOIL method

Grid method

$\times$	x	-3
x	x^2	$-3x$
$+6$	$6x$	-18

$x^2 + 6x - 3x - 18$ **simplify** $x^2 + 3x - 18$

Converting fractions to recurring decimals

Convert $5/11$ to a decimal

$$\begin{array}{r} 11 \overline{) 5.0000} \\ - 0 \\ \hline 50 \\ - 44 \\ \hline 6 \\ 60 \\ - 55 \\ \hline 5 \\ \vdots \end{array}$$

① $50 \div 11 = 4$ remainder 6
($50 - 44 = 6$)

② $60 \div 11 = 5$ remainder 5
($60 - 55 = 5$)

③ remainder repeats, so 45 repeats

$\frac{5}{11} = 0.4\dot{5}$

Simplifying algebraic fractions by factorising

Example

Simplify $\frac{3t+6}{3t}$

The numerator of this fraction will factorise as there is a common factor of 3.

This give $\frac{3(t+2)}{3t}$

Now, there is clearly a common factor of 3
Cancelling this through the fraction gives $\frac{t+2}{t}$

There are no more common factors in this expression. Note t cannot be cancelled as there is no t term in the +2 in the numerator.

Adding and subtracting algebraic fractions

In order to add or subtract any fractions, including algebraic fractions, we must ensure that the fractions have a **common denominator**.

Example $\frac{5}{a} - \frac{b}{a} = \frac{5-b}{a}$

The fractions $\frac{5}{a}$ and $\frac{b}{a}$ already have a common denominator a , so we just subtract the numerators.

Example $\frac{3}{2a} + \frac{3a}{4b}$

These fractions **do not** have a common denominator - the first step is to find the LCM of $2a$ and $4b$ and use this as a common denominator.

$\times 2b$ $\frac{3}{2a} + \frac{3a}{4b} = \frac{6b}{4ab} + \frac{3a^2}{4ab} = \frac{3a^2 + 6b}{4ab}$

Once there is a common denominator, add the numerators.
